FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "Global Experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The Global Experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the Global Experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the Global Experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Central Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Central Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to: provide guidance for ongoing and future research; predict the performance of existing and proposed pond systems subject to specific inputs and constraints; and improve the operation and efficiency of pond culture systems.

The Global Experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the CRSP Central Data Base and to present interpretations of site specific results. The Pond Dynamics/Aquaculture CRSP has conducted the Global Experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each CRSP site. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in CRSP Work Plans One to Three, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each Data Report will include one cycle (wet and dry seasons) of the Pond Dynamics/Aquaculture CRSP Global Experiment. Therefore, with few exceptions, each project site will have three Data Reports devoted to it, representing the results of the three cycles of the Global Experiment. Cycle I of the Global Experiment in Rwanda is presented in this volume.

INTRODUCTION

The Rwanda project is one element of the Pond Dynamics/Aquaculture CRSP. The long-range goal of the CRSP is to increase the availability of animal protein in less developed countries through a better understanding of pond processes over a wide range of tropical environments. The primary objective of Cycle I investigations was to estimate the natural production and variability of ponds. The investigations were designed to calibrate the pond systems and establish a data base that could be used as a basis for more complex experiments.

MATERIALS AND METHODS

Standardized experiments were conducted at all seven CRSP sites. In Rwanda, the methods and frequency of measuring each variable followed the CRSP protocol, which is available in Volume I of Collaborative Research Data Reports.

Twenty-one ponds, 40 x 15 x 0.90 meters, were constructed at the Rwasave Fish Culture Station on the Butare campus of the Universite Nationale du Rwanda. Routine measurements made throughout the year included: rainfall, air temperature, water temperatures, solar radiation, and wind speed. An extensive series of limnological measurements accompanied the Cycle I experiments (Appendix). Soil samples also were taken of the pond bottoms before and after each set of experiments.

The original experimental design for the Cycle I experiments included the estimation of seasonal differences between wet and dry seasons on fish production, and biological, chemical, and physical conditions. Delays in pond construction resulted in postponing the estimation of differences between wet and dry seasons. Instead, two experiments, each lasting 150 days, were conducted to estimate natural production levels on an annual basis.

Ponds were stocked with *Oreochromis niloticus* (*Tilapia nilotica*) males that weighed 30 to 40 grams. The sex of the fish was established by two independent examinations. Fish were randomly selected to be stocked in specific ponds. All ponds received triple super phosphate fertilizer at the low level of 8 kg/ha/month to decrease wide differences in natural variability.

RESULTS

Temperature

The 1,700 meter elevation at the Rwasave Station creates a cool, moist, tropical environment throughout most of the year. Rwanda has a distinct but brief dry season that typically occurs from June through August (Figure 1). The first experiment began on 26 February 1986 and terminated on 22 July. Rainfall in April was intense, averaging 1.4 cm/day, but there were only traces of rainfall in June and July. The average rainfall in the first experiment was 0.40 cm/day, and the average rainfall during the second experiment (1 October to 26 February) was 0.34 cm/day.

Solar radiation was highest from October until January, and lower levels were measured with the dense cloud covers and rainfall of March and April (Figure 2). Higher solar radiation levels might have been expected from June to August, the dry season, but dust and hazy conditions resulted in moderate light levels.

Mean pond temperatures for Experiment 1 were significantly lower in June and July, experimental weeks 17 to 22 (Figure 3), when mean pond temperatures ranged between 16.7°C (SD = 0.48) and 20.8°C (SD = 0.37). The lack of cloud cover in these dry months permitted maximum night radiation resulting in low pond temperatures. Dust particles in the atmosphere permitted only moderate day solar radiation, but did little to decrease night radiation. Ponds were typically thermally stratified during the day, but mixed during the night. The thermal stratifications resulted in a temperature difference of several degrees between the surfaces and bottoms of the ponds (Figures 4 and 5). The relationship between maximum top and minimum bottom temperatures to mean pond temperatures indicates the thermal range of environments available to *O. niloticus* in Rwandan ponds at an elevation of 1700 meters.

Dissolved oxygen

Dissolved oxygen (DO) remained at moderate concentrations during both Cycle I experiments. Increases in production caused by the low levels of phosphate added to the ponds did little to increase night pond respiration and decrease DO concentrations. The difference between surface and bottom DO measurements in the second experiment indicates an increased oxygen demand of the bottom sediments. This was probably a result of sediments in the newly constructed ponds that were beginning to acquire enough unoxidized organic matter to exert a higher oxygen demand on the water column. The differences in surface and bottom DO concentration are evident after week 17 in the first experiment (Figure 6), and are evident throughout the second experiment (Figure 7).

Fish Growth and Production

The rate of change in fish weight over the 150 days was similar for both experiments (Figure 8). *O. niloticus* stocked in the first experiment were about 10 grams heavier than those stocked in the second experiment (Table 1), but this did not seem to affect the rate of growth. The estimated mean net production for the first experiment was higher (2.04 kg/ha/day, SE = 0.20) than the second experiment (1.50 kg/ha/day, SE = 0.20).

Variability Between Individual Ponds

Duncan's Multiple Range Test was used to determine significant differences (Alpha = 0.05) between mean values of each pond. With few exceptions, there were significant differences in measured variables between ponds. During the first experiment, ammonia, primary production, and maximum bottom temperatures were not significantly different between ponds. In the second experiment, total phosphorus was the only variable that was not significantly different between ponds.

Pond C7 had the lowest mean fish weight (37.6 gm/fish) in Experiment 1, and the second lowest mean fish weight (49.5 gm/fish) in Experiment 2 (Table 4). By contrast, B1 had the highest mean fish weight in both experiments. The ranking of ponds on the basis of mean fish weight at the conclusion of the experiments varied, but there was a general pattern. Ponds that ranked highest in fish production during Experiment 1 were the highest in fish production in Experiment 2.

Rankings of ponds on the basis of chlorophyll *a* and total hardness (Tables 2 and 3) showed Pond C7 to be lowest in chlorophyll *a* in both experiments and lowest in total hardness in Experiment 2. Pond B1 was highest in chlorophyll *a* in Experiment 1, but ranked fifth in Experiment 2. There was a good correlation between chlorophyll *a* and fish production ($r^2 = .664$), but other variables did not show any significant correlations.

DISCUSSION

The experimental fish ponds at Rwasave Station are relatively cool for an equatorial environment, having a mean water temperature of about 21°C. Water temperatures were lowest during June, July, and August, but fish continued to grow during all seasons.

Fish production was greatest during Experiment 2 (October to February). Solar radiation during both experiments was comparable, but night radiation decreased pond temperatures during Experiment 1. Growth rates during Experiment 1 were probably affected because of the recent construction of the ponds, and the lack of organic content of the sediments. The effects of sediments on pond production could not be documented on the basis of soil samples taken before and after the experiments, but the lack of a sufficient aging period probably affected fish production in the ponds. However, the higher pond temperatures in the second set of experiments were probably most important in increasing fish production.

The Cycle I experiments were designed to estimate natural fish production over all seasons. Less critical but important objectives were to estimate the causative relationships between physico-chemical or biological factors and fish production. These relationships were difficult to establish although a suggestive relationship of chlorophyll *a* and fish production was shown for Experiment 1. It is necessary to increase the data base to clearly demonstrate a quantitative relationship between chlorophyll *a* and fish production.

Significant differences were found between environmental factors of individual ponds. Results from the two sets of experiments indicate that some difference between ponds are persistent and carry over to successive experiments. Residual effects of previous treatments will be superimposed on subsequent experiments conducted in the ponds. Higher treatment levels of organics or commercial fertilizers could overwhelm this base variability, but these persistent effects should be accounted for in later experiments. Removing or mixing bottom sediments may assist in reducing but may not eliminate these effects. Thus, the presence of those ponds persistently different from the rest should be recognized when assigning experimental treatments and when explaining results.
